## Description

## BACKGROUND OF THE INVENTION

[0001] This invention relates to an optical disk recording thereon compressed data of an image, and to an optical disk reproduction apparatus for reproducing the image data from the optical disk.

[0002] A so-called "CD-ROM" is a typical example of those systems which reproduce digital data by using an optical disk. The CD-ROM records data for a computer on an optical disk having the same physical format as CDs for audio use, and has the data format to be next described. A data string recorded on the optical disk comprises the smallest unit referred to as a "frame", and each frame contains digital data such as sync data, sub-code, main information and an error correction code.

[0003] Further, the CD-ROM employs the sector structure in which 98 frames (2,352 bytes) are gathered into 1 sector, and each sector comprises a 12-byte sync data, a 4-byte header data representing an address and a mode, a 2,048-byte digital data and a 288-byte error detection/ correction code.

[0004] On the other hand, a system comprising the combination of an inter-frame prediction with orthogonal transform, quantization and variable-length encoding is well known as an encoding system of moving picture, and an MPEG system of the ISO (International Organization of Standardization) is also based on this system. In the case of MPEG2, for example, the bit stream of the encoded image data is divided into six hierarchical layers, i.e. a sequence layer, a GOP (Group of Pictures) layer, a picture layer, a slice layer, a macro-block layer and a block layer. Among them, the GOP layer contains three kinds of data, that is, an I picture encoded from the information alone without using inter-frame prediction, a P picture generated by executing prediction from the I picture or P picture and a B picture generated by bidirectional prediction. The sequence layer comprises a GOP containing image data starting from the I picture and obtained by gathering the I picture, the P picture and B picture into one group, and an SH (Sequence Header) added to the leading part of the GOP.

[0005] EP-A-606 868, for example, discloses a picture coding method and decoding method and a picture signal recording medium. A signal is first encoded according to the MPEG system and then data only of an I-picture or of both of an I-picture and a P-picture or P-pictures is treated as data for high speed reproduction separately from data of the other pictures and are collectively recorded in units.

[0006] When moving picture are converted to compressed image data by high efficiency encoding, there is known a system which encodes the signal by reducing a compression ratio for scenes having vigorous motion, or in other words, at a high transfer rate, and by increasing the compression ratio for scenes having small motion, or in other words, at a low transfer rate. The variable

transfer rate compressed image data so encoded can reduce image deterioration due to compression in comparison with compressed image data of a fixed transfer rate obtained by fixing the compression ratio at a mean value.

[0007] An apparatus for recording the compressed image data having the variable transfer rate or the fixed transfer rate into the optical disk such as the CD-ROM and reproducing the data has been announced already.

## SUMMARY OF THE INVENTION

[0008] The prior art technology described above does not particularly consider so-called "trick play" such as n-time speed variable speed reproduction with respect to standard speed reproduction or reverse reproduction of the image data recorded on the optical disk. In reproduction of the image data, for example, n-time speed variable speed reproduction or reverse reproduction is generally required besides continuous reproduction of a standard speed, and a reproduction apparatus which satisfies these requirements becomes necessary. High speed retrieval is also required for the retrieval operation.

[0009] It is an object of the present invention to provide an optical disk and an optical disk reproduction apparatus each of which can conduct various kinds of trick play of the optical disk recording thereon compressed image data, and can make a retrieval operation at a high speed.

[0010] This object is achieved by an optical disk according to claim 1 and an optical disk reproducing apparatus according to claim 2.

[0011] According to one aspect, the optical disk records specific information necessary for trick play into an arbitrary area such as a TOC (Table of Contents) or a leading sector (sector 0) of the optical disk, and adds a sector address to each sector.

[0012] According to another aspect, the optical disk reproduction apparatus includes means for extracting and reproducing an I picture, a P picture and a B picture contained in a GOP layer inside a bit stream of compressed image data by looking up a trick play table.

[0013] After the optical disk is loaded to the optical disk reproduction apparatus, a system microcomputer first reads the trick play table recorded on the optical disk and stores it into a work area. When trick play is effected, the address of the sector to be read out is determined by looking up the necessary trick play table, and the address is retrieved on the optical disk so as to reproduce an image.

[0014] Because the address of the sector to be read out is determined by looking up the trick play table during trick play other than normal reproduction, trick play can be easily executed, and a retrieved reproduction image can be quickly obtained in the retrieval operation.

## BRIEF DESCRIPTION OF THE DRAWINGS

[0015]

Fig. 1 is a diagram showing a first embodiment of an optical disk according to the present invention;  
 Fig. 2 is a diagram showing a second embodiment of the optical disk according to the present invention;  
 Fig. 3 is a diagram showing a third embodiment of the optical disk according to the present invention;  
 Fig. 4 is a diagram showing a fourth embodiment of the optical disk according to the present invention;  
 Fig. 5 is a diagram showing a fifth embodiment of the optical disk according to the present invention;  
 Figs. 6A and 6B are diagrams each showing a sixth embodiment of the optical disk according to the present invention;  
 Fig. 7 is a schematic view showing a data format of the optical disk according to the seventh embodiment of the present invention;  
 Fig. 8 is a schematic view showing the data format of the optical disk according to the eighth embodiment of the present invention;  
 Fig. 9 is a schematic view showing the data format of the optical disk according to the ninth embodiment of the present invention;  
 Fig. 10 is a schematic view of tracks on an optical disk according to the present invention; and  
 Fig. 11 is a flowchart of an operation at the time of trick play.

## DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0016] Hereinafter, some preferred embodiments of the present invention will be explained with reference to the accompanying drawings. First, the embodiment shown in Fig. 1 will be explained.

[0017] Fig. 1 shows an optical disk according to the first embodiment of the present invention. The diagram shows a table for trick play on the optical disk. This trick play table records the numbers of pieces of music and movements (indices) and corresponding sector addresses for all the pieces and movements recorded on the optical disk, for example. Sector addresses are added to each sector of the optical disk, and this trick play table is recorded in an area such as a TOC (Table of Contents) or a leading sector (sector 0) of the disk.

[0018] When this optical disk is loaded to an optical disk reproduction apparatus, a system microcomputer first reads the trick play table and stores it in a work area. When trick play is effected, the address of the sector to be read out is determined by looking up this trick play table and is then retrieved on the optical disk so as to reproduce an image.

[0019] Because the address of the sector to be read out is determined by looking up the trick play table, re-

trieval can be carried out at a high speed.

[0020] Fig. 2 shows the optical disk according to the second embodiment of the present invention. The drawing shows the trick play table on the optical disk. The trick play table records all the sector addresses of the data recorded on the optical disk and the corresponding time codes. This trick play table is recorded in an area such as the TOC (Table of Contents) or the leading sector (sector 0) of the disk.

[0021] When this optical disk is loaded to the optical disk reproduction apparatus, the system microcomputer first reads the trick play table and stores it in the work area. When trick play is effected, the address of the sector to be read out is determined by looking up this trick play table, and the address is retrieved on the optical disk so as to reproduce the image.

[0022] Because the address of the sector to be read out is determined by looking up the trick play table during trick play other than normal reproduction, trick play can be easily conducted, and retrieval can be made at a high speed.

[0023] When compressed image data of a variable transfer rate is reproduced, the sector address cannot be determined from the time code because the sector address and the time code do not have a proportional relationship, and correct retrieval cannot be made. However, the corresponding sector address can be obtained by looking up the trick play table of this embodiment, and retrieval can be correctly made.

[0024] Fig. 3 shows the optical disk according to the third embodiment of the present invention. The drawing shows the trick play table on the optical disk. The trick play table records all the sector addresses of the data recorded on the optical disk and their contents. This trick play table is recorded in an area such as the TOC (Table of Contents) or the leading sector (sector 0) of the disk.

[0025] When the optical disk is loaded to the optical disk reproduction apparatus, the system microcomputer first reads the trick play table and stores it into the work area. When retrieval is effected, the address of the sector to be read out is determined by looking up the trick play table, and this address is retrieved on the optical disk so as to reproduce the image.

[0026] Because the address of the sector to be read out is determined by looking up the trick play table during trick play other than normal reproduction, trick play can be easily conducted and retrieval can be made at a high speed.

[0027] Fig. 4 shows the optical disk according to the fourth embodiment of the present invention. The drawing shows the trick play table on the optical disk. The trick play table records an SH (Sequence Header) added to the leading part of a GOP recorded on the optical disk and its sector address. This trick play table is recorded in an area such as the TOC (Table of Contents) or the leading sector (sector 0) of the disk.

[0028] When the optical disk is loaded to the optical disk reproduction apparatus, the system microcomputer

first reads the trick play table and stores it in the work area. When retrieval is conducted, the address of the sector to be read out is determined by looking up the trick play table, and the address is retrieved on the optical disk so as to reproduce the image.

[0029] Because the address of the sector to be read out is determined by looking up the trick play table during trick play other than normal reproduction, trick play can be easily conducted and retrieval can be made at a high speed.

[0030] Fig. 5 shows the optical disk according to the fifth embodiment of the present invention. The drawing shows the trick play table on the optical disk. The trick play table records the sector addresses of the start and the end of an I picture recorded on the optical disk. This trick play table is recorded in an area such as the TOC (Table of Contents) or the leading sector (sector 0) of the disk.

[0031] When the optical disk is loaded to the optical disk reproduction apparatus, the system microcomputer first reads the trick play table and stores it into the work area. When retrieval is conducted, the address of the sector to be read out is determined by looking up this trick play table, and the address is retrieved on the optical disk so as to reproduce the image.

[0032] Because the sector address of the I picture is determined by looking up the trick play table during trick play other than normal reproduction, trick play can be made by extracting only the I picture. The sector addresses of a B picture and a P picture can be recorded in the trick play table, and trick play can be carried out smoothly.

[0033] Figs. 6A and 6B show the optical disk according to the sixth embodiment of the present invention. Fig. 6A schematically shows the tracks on the optical disk. The tracks are spirally formed on the optical disk. Fig. 6B schematically shows a plurality of trick play tables 1, 2, 3 recorded in the tracks and their identification codes T1, T2, T3. When the optical disk is loaded to the optical disk reproducing apparatus, the system microcomputer reads the trick play tables recorded in the optical disk and stores them into the work area. In this instance, the system microcomputer can identify each trick play table by its identification code and can store it to a predetermined address of the work area. Therefore, even when any kinds of trick play tables exist, the system microcomputer can identify each table and can store it into the work table. In other words, the system microcomputer can determine the address of the sector by looking up a necessary trick play table during trick play and can easily effect trick play and at the same time, retrieval can be made at a high speed.

[0034] Fig. 7 shows the optical disk according to the seventh embodiment of the present invention. Fig. 7 schematically shows the data format recorded in the track on the optical disk. Each sector is further divided into blocks. The blocks contain a sync signal (Sync), a sector address (SA), a block address (BA), a parity (P),

digital data (Data) and an error correction code (ECC). The same address is recorded for each block for the sector address.

[0035] Fig. 8 shows the optical disk according to the eighth embodiment of the present invention. Fig. 8 schematically shows the data format recorded in the tracks on the optical disk, and each sector is further divided into blocks. The blocks contain the sync signals (S0, S1), the sector address (SA), the block address (BA), the parity (P), the digital data (Data) and the error correction code (ECC). The sector address is recorded in two blocks and SA1 and SA2 together represent one address. Therefore, in comparison with the seventh embodiment wherein the same address is written for each block, the sector address may be written into every two blocks, and redundancy of the address is smaller and the address area can be made smaller than in the seventh embodiment.

[0036] Fig. 9 shows the optical disk according to the ninth embodiment of the present invention. Fig. 9 schematically show the data format recorded in the tracks on the optical disk. Each sector is further divided into blocks. The blocks contain the sync signals (S0, S1, S2), the sector address (SA), the block address (BA), the parity (P), the digital data (Data) and the error correction code (ECC). The sector address is recorded into two blocks, and SA1, SA2 and SA3 together represent one address. Therefore, the same block address may be written into every two blocks. Accordingly, redundancy of the address is smaller and the address area can be made smaller than in the seventh and eighth embodiments.

[0037] Fig. 10 schematically shows the tracks on the optical disk, and the spiral track is formed on the optical disk. Symbols  $(x - 1)$ ,  $x$ ,  $(x + 1)$ , ...,  $(x + n)$  and  $(x + n + 1)$  represent sectors, respectively, and the data are reproduced in this sequence during normal reproduction.

[0038] Hereinafter, the trick play operation will be explained about the operation at the time of reproduction at an  $n$ -time reproduction speed. It will be assumed that a command of reproduction at an  $n$ -time is inputted while the sector  $x$  is being reproduced in Fig. 10. First, after the data of the sector  $x$  is read out,  $(x + n)$  as the next target sector is retrieved by track jump, or the like. The distance  $n$  from the initial position to the target sector is calculated by the system microcomputer in accordance with at which multiple speed the reproduction is to be made. After retrieval is so made, the data of the sector  $(x + n)$  is read out and  $(x + 2n)$  as the next target sector is again retrieved. Therefore, this operation is repeatedly carried out.

[0039] When the optical disk is loaded to the optical disk reproduction apparatus, the system microcomputer first reads the trick play table recorded on the optical disk and stores it into the work area. When trick play is conducted, the address of the sector to be read out is determined by looking up the necessary trick play table, and its address is retrieved on the optical disk so as to

reproduce the image.

[0040] Fig. 11 shows the flowchart of the operation during the n-time speed reproduction described above. Here, symbol m represents a frame (field) interval of the I picture. When the command of n-time speed reproduction is inputted from an external input device such as a remote controller, whether the relation  $m = n$  is first judged. When the result is  $m = n$ , only the I picture is retrieved by the trick play table and reproduction is carried out. When the result is  $m < n$ , the I picture is skipingly retrieved and reproduced by the trick play table. When the result is  $2m = n$ ,  $3m = n$ , and so forth, only the I picture is retrieved and reproduced. When the P picture is further retrieved and reproduced skipingly in addition to the I picture at this time, various speed reproduction can be made smoothly. When the result is  $m > n$ , the P picture is skipingly retrieved and reproduced by the trick play table in addition to the I picture. When the B picture is further retrieved and reproduced skipingly in addition to the I picture and the P picture at this time, various speed reproduction can be smoothly made. Thereafter, the operation described above is repeated if the n-time speed reproduction continues.

[0041] Though the explanation given above deals with the n-time speed reproduction operation, the present invention can be easily applied to reproduction in the reverse direction when n in the n-time speed reproduction is negative (-). Further, slow reproduction can be made when  $|n| < 1$ .

[0042] As described above, when retrieval is made by looking up the trick play table, image reproduction of the GOP unit can be easily made in the image data encoded by the MPEG system, for example. Therefore, besides the normal speed continuous reproduction operation, operations trick play such as slow reproduction, high speed reproduction, reproduction in the reverse direction, and the high speed retrieval operation become possible.

[0043] The present invention is not particularly limited to the foregoing embodiments but can be changed or modified in various ways without departing from the scope thereof.

[0044] In the optical disk according to the present invention, information necessary for trick play is recorded in an arbitrary area such as the TOC (Table of Contents) or the leading sector (sector 0) of the disk, and the sector address is added to each sector. The optical disk reproduction apparatus looks up the trick play table, and extracts and reproduces the I picture, P picture and B picture contained in the GOP layer inside the bit stream of the compressed image data. Accordingly, the present invention can easily execute trick play such as slow reproduction, high speed reproduction, reproduction in the reverse direction and the retrieval operation. It is obvious in the explanation given above that the image data may be the moving picture or the still picture. It is further obvious that the present invention can be similarly applied to the audio data or control data carried by the im-

age data.

## Claims

1. An optical disk having main information which consists of several sectors and a sector address recorded in each of respective sectors thereon, wherein:

said main information includes at least compressed image data having a variable transfer rate;

said optical disk has a table containing information correlating said sector addresses and time code of the compressed data, a relationship between said sector addresses and said time code being inconstant; and

image data associated with a desired time code can be selectively reproduced by looking up the table correlating said sector addresses and said time code.

2. An optical disk reproducing apparatus for reproducing image data from the optical disk recorded therein, said image data consisting of a plurality of sectors arranged on said optical disk, and a sector address recorded in each of respective sectors thereon, said image data at least comprising compressed image data having a variable transfer rate, and said optical disk has a table containing information correlating said sector addresses and time code of the compressed data, a relationship between said sector addresses and time code being inconstant, said apparatus comprising:

means for detecting the sector address to be read out of a desired image data associated with a desired time code; and

means for retrieving the detected address on the optical disk so as to reproduce an image.

## Patentansprüche

1. Optische Platte, welche eine Hauptinformation aufweist, die aus mehreren Sektoren besteht und einer Sektoradresse, die in jedem von entsprechenden Sektoren davon aufgezeichnet ist, wobei:

die Hauptinformation zumindest komprimierte Bilddaten beinhaltet, die eine variable Transfer-rate aufweisen, wobei

die optische Platte eine Tabelle aufweist, die Informationen enthält, die die Sektoradressen und einen Zeitcode der komprimierten Daten verbindet, wobei eine Beziehung zwischen den Sektoradressen und dem Zeitcode nicht kon-

stant ist, und  
 Bilddaten, die mit einem gewünschten Zeitcode  
 assoziiert sind, selektiv reproduziert werden  
 können durch Nachlesen in der Tabelle, die die  
 Sektoradressen und den Zeitcode verbindet.

5

2. Reproduziergerät für eine optische Platte zum Re-  
 produzieren von Bilddaten von der optischen Platte,  
 die darin aufgezeichnet sind, wobei die Bilddaten  
 aus einer Mehrzahl von Sektoren bestehen, die auf  
 der optischen Platte angeordnet sind, und einer  
 Sektoradresse, die in jedem entsprechender Sek-  
 toren darauf aufgezeichnet ist, wobei die Bilddaten  
 zumindest komprimierte Bilddaten aufweisen, die  
 eine variable Transferrate aufweisen, und wobei die  
 optische Platte eine Tabelle aufweist, die Informa-  
 tionen enthält, die die Sektoradressen und den Zeit-  
 code der komprimierten Daten verbinden, wobei ei-  
 ne Beziehung zwischen den Sektoradressen und  
 dem Zeitcode nicht konstant ist, wobei das Gerät  
 aufweist:

10

15

20

Mittel zum Detektieren der Sektoradresse, die  
 auszulesen ist von einer gewünschten Bildda-  
 ten-Einheit, die mit einem gewünschten Zeitco-  
 de assoziiert ist; und  
 Mittel zum Abrufen der detektierten Adresse  
 auf der optischen Platte, um ein Bild zu repro-  
 duzieren.

30

## Revendications

1. Disque optique ayant des informations principales  
 qui sont constituées de plusieurs secteurs et d'une  
 adresse de secteur enregistrée dans chacun des  
 secteurs respectifs situés sur celui-ci, dans lequel :

35

lesdites informations principales incluent au  
 moins des données d'image compressées  
 ayant une vitesse de transfert variable,  
 ledit disque optique a une table contenant des  
 informations mettant en corrélation lesdites  
 adresses de secteurs et un temps de présen-  
 tation des données compressées, une relation  
 entre lesdites adresses de secteurs et ledit  
 temps de présentation étant inconstante, et  
 des données d'image associées à un temps de  
 présentation voulu peuvent être sélectivement  
 produites en recherchant la table mettant en  
 corrélation lesdites adresses de secteurs et le-  
 dit temps de présentation.

40

45

50

2. Dispositif de lecture de disque optique pour lire à  
 partir du disque optique des données d'image qui y  
 sont enregistrées, lesdites données d'image étant  
 constituées d'une pluralité de secteurs agencés sur  
 ledit disque optique, et une adresse de secteur en-

55

registrée dans chacun des secteurs respectifs si-  
 tués sur celui-ci, lesdites données d'image compor-  
 tant au moins des données d'image compressées  
 ayant une vitesse de transfert variable, et ledit dis-  
 que optique a une table contenant des informations  
 mettant en corrélation lesdites adresses de sec-  
 teurs et un temps de présentation des données  
 compressées, une relation entre lesdites adresses  
 de secteurs et ledit temps étant inconstante, ledit  
 dispositif comportant :

des moyens pour détecter l'adresse de secteur  
 à extraire de données d'image voulues asso-  
 ciées à un temps de présentation voulu, et  
 des moyens pour récupérer l'adresse détectée  
 sur le disque optique de manière à lire une ima-  
 ge.
